DistCache: Provable Load Balancing for Large-Scale Storage Systems with Distributed Caching

Alan (Zaoxing) Liu

Zhihao Bai, Zhenming Liu, Xiaozhou Li, Changhoon Kim, Vladimir Braverman, Xin Jin, Ion Stoica
Large-scale cloud services need large storage clusters

- Major cloud services serve billions of users.

![Large datacenter clusters](image-url)
Storage servers have load imbalance issue

- Typical workloads [Sigmetrics’12]:
  - Highly skewed.
  - Dynamic.

The skewness of the workload brings imbalance
Solutions to mitigate the load imbalance

- Consistent hashing and related.
  - Do not handle dynamic and skewed workloads.

- Data migration or replication.
  - Large system and storage overhead.
  - High cache coherence cost.

- Front-end cache as a load balancer.
  - Low update overhead.
  - Work for arbitrary workloads.

  - Low update overhead.
  - Work for arbitrary workloads.
Prior work: Fast, small cache alleviates load imbalance

Cache hottest $O(n \log n)$ items [SoCC’11]

Server load is balanced

$n$ servers

Application to cluster-scale: [NSDI’16, SOSP’17]

A cache node brings load balancing in a cluster.
Strawman: Big, fast cache for inter-cluster load balancing
One “Big” cache is infeasible

One big cache is not scalable.
First, balance the load within each cluster.
Second, balance the load between clusters

Cache hottest $O(m \log m)$ items.

We need to avoid using big node anywhere.
DistCache: Distributed caching as load balancer

Cache hottest $O(m \log m)$ items.

Upper-layer cache nodes

Lower-layer cache nodes

$m$ clusters

Provable, Practical, General mechanism.
Ideally, DistCache should be as good as "one big cache" to absorb $O(m \log m)$ hottest items.
Ideally, DistCache should be as good as “one big cache” to absorb $O(m \log m)$ hottest items.

To achieve “one big cache”:
- Support **ANY** query workload to hottest $O(m \log m)$ items.
- Each cache node is **NOT** overloaded.
- Keep cache coherence with **MINIMAL** cost.
Design Challenges of DistCache

- Challenge #1: How to allocate cached items?
  - Do not overload any cache node.
  - Do not incur high cache coherence cost.

- Challenge #2: How to query the cached items?
  - Provide best and stable cache query distribution.

- Challenge #3: How to update the cached items?
  - Two-phase update to ensure cache coherence.
Design Challenges of DistCache

- Challenge #1: How to allocate cached items?
  - Do not overload any cache node.
  - Do not incur high cache coherence cost.

- Challenge #2: How to query the cached items?
  - Provide best and stable cache query distribution.

- Challenge #3: How to update the cached items?
  - Two-phase update to ensure cache coherence.
Challenge #1: How to allocate the cached items?

Strawman Sol #1: Cache-Replication

Upper layer cache nodes

{A, B, C, D, E}  
Update cache

{A, B, C}  
Update cache

Lower layer cache nodes

{A, B, C}  
Update cache

{D, E}  
Update cache

{F}  
Update cache

Cache-Replication incurs high cache coherence cost.
Challenge #1: How to allocate the cached items?

Strawman Sol #2: Cache-Partition

Cache-Partition could put too many hottest items into the same cache node.
Independent hashes to allocate the cached items

Two independent hashes $H1$ and $H2$ to allocate hot items

Upper layer cache nodes
- $\{B, E\}$
- $\{A\}$
- $\{C, D, F\}$

Lower layer cache nodes
- $\{A, B, C\}$
- $\{D, E\}$
- $\{F\}$

- Stable and best cache allocation.
- Small cache coherence cost.
Challenge #2: How to query the cached items?

Query item with upper layer first does not guarantee best throughput.
Power-of-two-choices to query the cached items

Get(C) from the node with less load

Power-of-two-choices to route the queries guarantee stable throughput.
Putting together: DistCache

- Independent hashes to allocate cache items.
- Power-of-two-choices of current cache loads to route queries.
Theoretical Guarantee behind DistCache

For m storage clusters:
  o DistCache absorbs any query workload to the hottest $O(m \log m)$ items.

with the following condition:
  o Query rate for a single item is no larger than $\frac{1}{2}$ of one cache node’s throughput. (No more half of a cluster!)
Proof Sketch: Convert to a perfect matching problem

Proofs leverage tools from expander graph, network flow, and querying theory.

Our PoT query can find a perfect match for any query workload distribution.

Upper layer cache nodes

Lower layer cache nodes
Remarks of the DistCache Analysis

- The numbers of cache nodes in two layers can be different as long as $m$ isn’t too small.

- The throughput of cache nodes can be different.

- Aggregated throughput is almost same as “big cache”.
Example Deployment Scenarios of DistCache

Cache

DRAM/SSD Array

O(10) MQPS each

Programmable Switch

O(1) BQPS each

Servers

+ 

O(100) KQPS each

Flash / Disk

+ 

O(10) MQPS each

DRAM
Case Study: Switch-based distributed caching

1. Client sends query
2. Client side switch decides which cache node to access (PoT)
3. If cache hit, switch will reply

When cache hit, cache switch will reply the query immediately
Case Study: Switch-based distributed caching

1. Client sends query
2. Client side switch decides which cache node to access (PoT)
3. If cache miss, query is forwarded to server
4. Server handles the query to Redis, and replies.

When cache miss, query is handled by the server
Implementation Overview

- **Controller**
  - Cache Management
  - Network Management
- **Cache**
  - Key-Value Cache
  - Heavy Hitter Detector
  - Query Routing
- **Switch**
  - Cache Switch
  - Client-side Switch
- **Servers**
  - Connections
- **Clients**
  - Connections

- **Features**
  - Query Load Statistics
  - Query Routing
P4: Programmable Protocol-Independent Packet Processing

User-defined Packet Format:

<table>
<thead>
<tr>
<th>ETH</th>
<th>IP</th>
<th>TCP</th>
<th>SEQ</th>
<th>OP</th>
<th>KEY</th>
<th>VALUE</th>
</tr>
</thead>
</table>

P4: Programmable Protocol-Independent Packet Processing

User-defined Packet Format:

- ETH
- IP
- TCP
- SEQ
- OP
- KEY
- VALUE

Existing Packet Header
Packet Header for Caching

Match:
OP == GET
Action: Get_Load ++

Match:
KEY == A & Valid
Action: Get value of A

Match:
Val of A is fetched
Action: Update to header
Evaluation Setup

Baselines: NoCache, Cache-Partition, Cache-Replication.
Evaluation Takeaways

- For read queries, DistCache works as good as Cache-Replication.

- For write queries, DistCache has performed significantly better:
  - When write ratio (<0.3), better throughput.
  - When write ratio (>0.3), as good as Cache-Partition.
DistCache balances the loads of different clusters

DistCache offers nearly perfect throughput for skewed workloads
DistCache scales linearly with the number of nodes.

DistCache can support very large storage clusters.
DistCache incurs small cache coherence cost

Under Zipf-0.99 workload, DistCache offers best write throughput.
Conclusions

- DistCache is a general distributed caching mechanism to ensure load balancing crossing many storage clusters.

- DistCache requires simple primitives (independent hashing, power-of-two-choices routing).

- DistCache provides near-perfect throughput with rigorous theoretical guarantees.
